Housing Tips For Small Poultry Flocks

By R. Scott Beyer, Poultry Specialist

Some designs are simple, relatively inexpensive, and easy to build. Others look good but are not all that functional. The worst designs fail to consider the most important criteria—the health and safety of the birds. In evaluating plans, here's what you need to consider to keep your flock safe, healthy, and productive.

**Keep Predators Out**—First, how well does the structure keep predators out? This is even more important than keeping birds in. Neighborhood dogs have probably killed more chickens in suburban areas than any other predator. Coyotes, skunks, foxes, raccoons, and hawks may try to steal an easy meal eventually. Lightweight cotton or plastic netting may hold birds, but it won’t keep predators from chewing through the fence. You may need to install wire or a high voltage electrified fence. Be sure to get the coop under cover, if predators are a serious threat. Some bird owners wouldn’t dream of keeping chickens without an electric fence.

Sooner or later, every housing system fails. Escapes are a serious threat. Until birds are caught and returned to the pen. Avoid this problem by installing a safety trap outside the pen. The enclosure, which operates like a minnow trap, should be placed at the base of the fence so the bird wanders in trying to find its way back into the pen.

**Features to Reduce Hazards**—The poultry house should be easy to clean, or chores may not get done as often as they should. In a well-designed house, manure collects in an area where it cannot be disturbed. It can be removed on trap or scraped out from a panel underneath and easily placed in a compost bin. Select a plan that features an egg box that opens from the outside. Not having to enter the pen each time reduces the risk of contamination. Also look for an egg collection box that can be moved from one side of the pen to the other, where it is not directly exposed to the sun. When you move the coop, move the egg box to the shady side. Another nice feature is a feeder or waterer you can fill from outside the pen.

**Protection from Weather Extremes**—Keeping heat out of the coop is more important than keeping heat inside. In Kansas, more birds have been killed by extreme summer heat than extreme winter cold. A basic rule in cold weather is to give birds protection from the wind. Combats and wattles freeze easily in high winds but survive at temperatures well below freezing when air is calm. Locate the exterior door so it does not face prevailing winter wind. Place an air deflector between windows and doors to protect the roost from high winds. Give birds a place to stay dry. When birds are unable to escape wet and windy conditions, they are less likely to survive winter.

Summer heat is an issue for birds in Kansas, especially heavy birds. Toward the end of the growth cycle, a Cornish—Rock Cross meat chicken may experience stress at 80 degrees F. Most heat enters through the roof and is where mains is weakest. With experience to the sun, heat can build up rapidly under the roofing material. The worst coop designs feature a low roof covered only with metal sheeting. The coop should also include a layer of rigid foam between the trusses and the roof. Adding all that heat to the interior defies the intent to keep the coop cooler all summer long. Beware of poultry house designs with a low roof that traps heat near the birds. Look for one with passive vents in the peak to allow heated air to rise and exit the coop. Avoid “chicken tractors.” These movable coops are typically not good for modern broilers. They are too low to the ground and retain excessive heat that can harm birds.

**Benefits of Portability**—You can move your small poultry flock easily from place to place by installing skids or wheels on your coop placing the house on a small trailer so it is easier to move. Chickens are destructive to their range area. Even a few birds can dig holes and scratch grass out quickly. Consider an outdoor run that is far enough away from the house. Move pen to keep parasites from building up in the soil and exposing birds to harm. A moveable coop can be moved to a shady area during the summer or protected from harsh winter conditions.

JUNE 2021
One Month Closer to Fair...and Summer Heat

Welcome to the month of June! Summer was and always has been my favorite time of year. Why? Well, summer is not just when I get to go to the lake and camp with my family. Summer is also fair season! During my time as a 4-Her in Russell county, I would always spend most of my summer taking care of my show cattle and preparing for the coming fair. Washing cattle was always the biggest chore in my mind. Could it be because my heifers seemed to always be the ones that disliked “bath time”? This could be a possibility. However, it was important to bathe them not just to keep them clean, but to keep them cool. During the summer, heat stress and bloat were key factors that I had to keep an eye out for. Summer heat stress caused cattle to reduce feed intake, thus lowering rate of gain, and bloat can lead to reduced feed intake and even death in some serious cases.

Frothy bloat is a condition that occurs when a ruminant consumes feeds that produce thick, foamy gas that the animal cannot pass by belching. This froth then builds in the rumen and causes noticeable discomfort and can become deadly if the pressure is not alleviated. According to a grazing management article, to reduce the risk of bloat, bloat-prevention agents such as ionophores and poloxalene can be added to feed and water to minimize the risk of bloat.

According to K-State Research and Extension beef veterinarian A.J. Tarpoff, heat stress often causes cattle to eat less, which also negatively affects their performance. According to Tarpoff, these are the best management practices for helping to reduce heat stress in cows:

- **Handling.** Receive, ship or move cattle only during the coolest parts of the day, preferably before 10 a.m.
- **Feeding.** Modify feeding times. Feed 70 percent of the animals’ ration as late in the evening as possible, which puts the peak heat of digestion overnight when temperatures are likely cooler. Decrease feeding during the day.
- **Managing heat.** Split cattle between pens or reduce stocking density. Maximize airflow by removing obstructions around facilities, including weeds. If feasible, install shade structures, which can reduce solar radiation and reduce the temperature on the pen’s floor. Install sprinklers to wet cattle down at night or early morning so as not to increase humidity.

Finally, water is also a key component when preventing heat stress. As a rule of thumb, Tarpoff recommends that cattle consume about five times the amount of water as the dry matter they are consuming. Tarpoff also explains that producers need to be prepared to increase the water tank capacity within a pen to meet the needs of cool, clean and readily-available water as water is critical during a heat stress event.

For more information on how to prevent bloat or heat stress, please contact me at the office or by email.

Best,

Shannon

June Ag Fact
Corn tortillas can differ in color based on the type of corn used. Some are white and others are yellow.
Sweet Corn Primer

It used to be simple to decide which sweet corn to plant. You simply chose a cultivar and planted when the soil temperature reached 55 degrees. Now it has become more complicated due to genetic advances in sweet corn. Breeders have found certain genes that improve “standard” sweet corn. Below is an overview of the types commonly available to homeowners.

Standard (su): This is our “old” sweet corn and contain a “sugary gene” (su). Standard sweet corn should be isolated from field corn, popcorn, supersweets and ornamental corn. To isolate one type of corn from another, do not plant one type within 200 to 250 feet or be sure to have a difference of 12 to 14 days in time to maturity. Plant when the soil temperature reaches at least 55 degrees. Recommended varieties include Honey and Cream, Silver Queen, Sterling Silver, Jubilee, or Merit.

Supersweet (sh2): Though supersweets have up to three times the sweetness of standard sweet corns and hold their sweetness longer after harvest due to the sh2 gene, they do have some drawbacks such as tougher kernels and a lack of some of that good “corn” flavor. They also need to be isolated from other sweet corn types and are very sensitive to cooler soils. Wait until the soil temperature reaches 65 degrees before planting. Try Candy Store, Florida Staysweet, Sugar Loaf, Sweet Time, or Sweetie.

Sugar Enhanced (se): These are probably the most popular type of sweet corn grown due to their tender kernels, good flavor and less sensitivity to cool soils (60 degree soil temperature for planting). They hold their post-harvest sweetness longer than standard types but will not hold sweetness as long as the supersweets. The sweetness from the sugar-enhanced types is due to the “se gene”. If both parents were se types, the variety is known as an se+ or se se. If only one parent was an se type and the other an su type, then the variety will be listed as se. They do not need to be isolated other than from the supersweets. Suggested varieties include Bodacious, Ambrosia, Sweet Temptation, Delectable and Miracle.

Triplesweet (synergistic): The newest types of sweet corns blend the su, se and supersweet types with the goal of combining the best characteristics of each. Try Serendipity, Polka, Avalon or Frisky. (Ward Upham)

Red Plastic Mulch and Tomatoes

Plastic mulches have long been known to provide advantages for the vegetable grower including earlier fruiting, increased yields and weed control. More recently advantages have been noted for colored mulches over the more traditional black plastic mulch. With tomatoes, the color choice has been red. Though normally there is an increase in production of marketable fruit with red mulch over black mulch, the amount of the increase varies with the type of year we have. There may be no increase during years of near-perfect weather or up to a 20% increase with less favorable growing conditions. A good average expected increase is about 12%.

So, how do you apply plastic mulch? Commercial growers have a mulch-laying machine that applies the trickle (drip) irrigation line and the mulch in one operation. Home gardeners must do this by hand. The first step after soil preparation is to place a trickle line near the center of where the mulch will lay as the plastic will prevent rainwater or overhead irrigation from reaching the plants. Then construct trenches for the outer 6 inches of the plastic mulch. This allows the center of the bed to be undisturbed with the edges of the mulch draping down into the trench. Fill the trenches to cover the edges of the mulch. This will prevent wind from catching and blowing the mulch. If the soil has been tilled, a hoe is all that is needed to prepare the trenches.
